Overview of Current Investigations

Understanding the flow of traffic through a highway interchange system is important for the design process and the smooth operation of the roadway. Currently, traffic engineers ignore entrance and exit ramps in the models by placing sensors upstream from exit ramps and downstream from entrance ramps. These sensors measure traffic density and speed. The goal of this project is to develop a continuum-based model of traffic flow that includes the effects of the ramps, greatly reducing the need for sensors. This reduces data collection costs and increases the flexibility of simulations. The model is an extension of Zhang's viscous model (Transportation Research Part B 37 (2003) 27-41).

Next generation power steering mechanisms rely upon torque sensors. The goal of this project is to develop analytical and computational models that determine the magnetic field intensity, magnetic flux density and flux linkage for a novel power steering assembly.
